Abstract: Dry stone-walled terraces are peculiar features of Mediterranean farmland, representing typical examples of social-ecological systems combining ecological functionality and ecosystem services provision. In the Shouf Biosphere Reserve (Lebanon) a program of restoration of abandoned terraces applying Forest Landscape Restoration (FLR) principles is ongoing from 2016, combined with biodiversity monitoring activities. This study illustrates preliminary results of the plant monitoring, with the aim to (1) draft a checklist of the plants found in the terraces, (2) compare plant diversity and evaluate consistency of species assemblages observed among 3 different terrace managements (abandoned, restored and intensively-cultivated) and (3) compare ecological and ecosystem service value of the plant communities in the 3 types of terraces. Overall, 332 species were observed, with significantly higher diversity found in abandoned and restored terraces compared to intensively farmed terraces. Similarly, species assemblages of restored terraces were closely related to abandoned and distantly related to intensively-managed terraces. According to the study, restored terraces provide the same ecological value and ecosystem services functions as abandoned terraces, significantly higher than intensively-managed terraces. This study showcases the effectiveness of FLR programmes in restoring economic and social functions of terraced Mediterranean farmland while maintaining ecological functionality.

Keywords: agricultural terraces, land abandonment, restoration, FLR, biodiversity, ecosystems services

Introduction

Agricultural smallholder terraces are peculiar features of Mediterranean cultural landscapes, enabling crop production in dry environments and steep slopes (García-Ruiz et al., 2020; Tarolli et al., 2014). Terraced croplands have thousands-year old tradition in the Mediterranean basin and are widespread across all Mediterranean cultures (Blondel, 2006;

Kladnik et al., 2017). Twelve UNESCO World Heritage Sites and two FAO's Globally Important Agricultural Heritage Systems (GIAHS) which feature terraced landscapes are found in the region. Terraced landscapes are typical examples of social-ecological systems which retain ecological functionality while providing several ecosystem services (ES) (Nieto-Romero et al., 2014). Beside food provisioning, ES provided by terraced landscapes include the reduction of soil loss, the increase of rainfall retention, the increase of plant biomass, the enrichment of the soil, the mitigation of fire, floods and desertification risks. Most notably, terraced landscapes ultimately represent a valuable adaptation strategy in face of the climate warming.

Two main types of terraces are used in the Mediterranean region, namely earth embankments and dry stone terraces, with possible use of mixed types (Cicinelli et al., 2021). Lebanon features dry stone walls as vertical elements to create horizontal strips of land cultivated with tree crops, such as mulberry (historically used for silk production), vines, olives, figs, walnut and, most recently, apple and cherries (Zurayk, 1994). In the last decades, agricultural transformations in the Mediterranean are led by two opposite drivers, i.e. the intensification of farming practices and the abandonment of economically marginal croplands (Debolini et al., 2018; Lomba et al., 2020; Otero et al., 2015; Plieninger et al., 2016; Reynolds et al., 2014). Lebanese terraced farmland has been affected by both drivers. In fact, after the WWII considerable migration of the population from the countryside to the coastal cities caused the abandonment of less accessible terraces. The abandoned terraces have suffered two different types of processes: (i) soil erosion due to the lack of maintenance of the stone walls and steep slopes, and (ii) fast secondary forest colonization on more stable terraces where the soil has been maintained, although the accumulation of dry biomass increases the risk of fires (Abdallah, 2012). Similar pattern are found across Mediterranean countries (Brunori et al., 2018; Heider et al., 2021; Modica et al., 2017; Rühl et al., 2006). According to the time of abandonment and the stability of the slopes, different deterioration stages are seen in the terraces. In some cases, stone walls have completely collapsed causing erosion and hindering colonization by serial shrubby vegetation. In other cases, with more stable slopes, the terraces remain invisible as they have been colonized by very dense secondary pine forests (*Pinus brutia*) and mixed communities of oaks (mainly *Quercus infectoria*, and to a lesser extent *Q. coccifera*) and pines. This phenomenon has relevant consequences on biodiversity and environmental risks. On one hand, dry stone-walls, together with other farmland microhabitats linked to sustainable farming practices (e.g. scattered trees in farmland plots, synanthropic vegetation such as the segetal plant communities of cultivated habitats, ruderal vegetation dominated by thistle-type species along cropping borders, roadsides, and disturbed lands, the vegetation of water ponds or water lines crossing terraced crops, and patches of woody vegetation surrounding terraced crops), represent themselves an important microhabitat which enhance farmland biodiversity (Solomou et al., 2020). On the other hand, farming practices have been usually intensified with the use of pesticides, fertilizers, irrigation, ploughing, the use of herbicides for the suppression of synanthropic vegetation, and the cementation of the stones of the walls destroying the habitats of their interstices. Farming intensification is universally acknowledged as one of the main threats to farmland biodiversity (IPBES, 2019), including in the Mediterranean basin (Henle et al., 2008; José-María et al., 2010). The transition from low-input to intensive practices in Lebanese terraced croplands started in the 1970s, after a grape phylloxera infestation affected vineyards, forcing landowners to shift to apple and cherry production, which require more intensive farming practices (Corrieri et al., 2021).

Stone-walled terraces are featured prominently in the Shouf Biosphere Reserve (SBR), the largest protected area of Lebanon, which corresponds to the 5% of the country area. In the western slope of the Shouf range (included in the Shouf District) terraces are present over the 10% of the land (Corrieri et al., 2021). In the early 1990s, almost 66% of terraces

in the area were already abandoned (Zurayk et al., 2001). The restoration of abandoned terraces plays a critical role in terms of enhancing ecosystem services to sustain both biodiversity and human livelihoods. In 2016 the SBR started a restoration program of abandoned terraces within the framework of a large-scale Forest and Landscape Restoration initiative, covering the 50,000 ha of the SBR (Hani et al., 2017, 2019, 2021). Overall, more than 150 ha of degraded dry-stone walls terraced were successfully restored. The restoration of dry stone-wall terraces in the SBR also included interventions for the maintenance and recovery of marginal habitats linked to the agriculture terraces, such as hedges, tree and shrub shelters, isolated trees, ruderal vegetation along roads, consistently with the FLR principles. Restored terraces have been being farmed sustainably, with low-input agricultural practices and high diversity of crops (fruit trees, olives, aromatic plants, vegetables).

In order to evaluate the effectiveness of the restoration activities to promote biodiversity and ecosystem services the SBR has launched a biodiversity monitoring program. This study illustrates preliminary outcomes of plant monitoring activities.

More specifically, the study aims at

- i. drafting a checklist of the plants found in the terraces of the western foothills of the SBR;
- ii. comparing plant diversity of restored terraces with abandoned and intensively-managed terraces;
- iii. test the similarity of plant communities among restored, abandoned and intensively-managed terraces and
- iv. evaluating the ecological and the ecosystem service value of the plant communities of restored terraces with respect to abandoned and intensively-managed terraces.

Material and Methods

Study area

The study area is located in the foothills of the western slope of the Shouf mountains, within the Development zone of the Shouf Biosphere Reserve (Mount Lebanon governorate, Shouf district). More in detail, study plots were located in the municipalities of Ain Zhalta, Barouk, Maasser al-Shouf, Baadarane, Mristi and Jbaa al-Shouf (Figure 1). From the ecological point of view, the area extends in the supra-Mediterranean bioclimatic zone, at an elevation between 1000 and 1200 m asl. The landscape is characterized by evergreen and deciduous oak forests (*Q. calliprinos* and *Q. infectoria*), pine forests (*P. pinea* and *P. brutia*) and mixed forests, replaced on vast areas by agricultural and pastoral land, which partially has undergone secondary vegetation succession. Agricultural terraces are cultivated with olives, fruit trees, vines and aromatic plants (lavender, rosemary, oregano). Species-rich communities of herbaceous plants are featured in recently abandoned agriculture terraces (chiefly in limestone substrates), while mid- and long-term abandoned agriculture/pasture lands are colonized by different types of woody vegetation depending on the period of abandonment (e.g. small thorny shrubs, high shrubs, with scattered trees, and forest stands).

Figure 1 - Map of the study area, with municipalities highlighted. Monitoring sites are shown in yellow. AB=abandoned terraces; RL=restored terraces; IN=intensively-managed terraces. Yellow dotted line represent the border of the SBR development zone. Inset: location of the SBR (in yellow) within the Lebanese territory.

Sampling methods

The plant communities of 18 dry stone-walled terraced fields (6 terraces of each of 3 management types) were monitored in 2020 and 2021. Terraces were classified as intensively managed (hereafter IN), abandoned (AB) or restored (RL). Intensively-managed terraces were cultivated with fruit trees (mainly apple, cherry, pear, plum), and, less frequently, with walnut, almond, olives or vines, applying intensive practices such as

deep ploughing, the use of fertilizers and pesticides, irrigation and weed control. Abandoned terraces included diverse stages of abandonment (~10 years to ~40 years). Restored terraces underwent restoration (stone wall restoration, organic soil replenishment, composting), reduced soil mobilization, soil mulching, limited or no use of agrochemicals, and diversified planting, combining aromatic and culinary shrubs such as lavender, oregano, sumac and rosemary, and fruit trees such as olives, almonds, figs, and vines in 2017 or 2018. One terrace only was restored in 2020. However, data collected in this terrace was subsequently discarded from the analysis, since the timing of the restoration did not allow for a complete regeneration of the herbaceous vegetation. The average terraced field size was 2500 m² (min 500, max 5000). Each terrace was visited 4 times each year (March to September). During each field visit (hereafter ‘inventory’), a representative sample of the terraces (several hundreds of square metres) was surveyed, and a checklist of plant species observed was compiled. The monitoring led to the compilation of a complete checklist of species present in each monitored terrace (hereafter ‘site’).

Data analysis

Species diversity. In order to compare species’ diversity across managements, we fitted a linear mixed model to predict the number of species observed in each inventory with the management type (AB, RL or IN). The model included the site as random effect. Data normality assumption check was performed by a Shapiro-Wilk test of normality. In addition, post-hoc multiple comparisons Tukey test with Bonferroni-Holm correction was eventually performed.

Similarities of plant communities. To evaluate the consistency and the similarities of the plant communities found in the three terrace managements we performed a hierarchical cluster analysis (‘complete linkage’ method) on a dissimilarity matrix computed on a species-site presence/absence matrix with the Bray-Curtis distance (Bray and Curtis, 1957; Faith et al., 1987), widely used in ecology and already applied in studies of plant communities’ composition (Cleland et al. 2013). In addition, an analysis of similarities (ANOSIM) was performed on the same dissimilarity matrix of species assemblage data (999 permutations). Decomposition of the Bray-Curtis dissimilarity was used to evaluate within-site similarity and between-site dissimilarity (Moser et al., 2007).

Ecological and ecosystem services value. To compare the ecological and the ecosystem service value of the plant communities across different managements we calculated an ecological (ECOL) and an ecosystem service (ES) value index for each plant species observed in the monitoring. Each index summarises several variables. Table 1 gives an overview of the variables included in the calculation of the indices. The ES value was evaluated by considering the 3 categories of ES, as defined by the Common International Classification of Ecosystem Services (CICES) (Haines-Young and Potschin, 2018), namely, the provisioning services, the regulation and maintenance services and the cultural services. For each ES typology we identified 2 to 5 indicators. Dichotomous indicators (yes/no) were coded with a binary value (yes=3, no=0). Indicators referred to continuous were ranked to ordinal variables. Values for “Pollination” were calculated as the nearest integer of the ln of the frequency of pollinating wildbee species known to feed on the plant species, according to Grace (2010). Similarly, values for “Melliferous” were computed by 1) calculating the frequency and the overall sum of the proportion of pollens found in 25 honey samples, as reported by Silici & Gökçeoglu (2007); 2) calculating the ln of the values of each of the two variables (frequency and overall proportion); 3) summing the two values and rounded it to the nearest integer. ECOL and ES indices were calculated by normalizing (0-1) the sum of the respective indicators. A “total” (TOT) index, which sums ECOL and ES indices, was eventually computed. For each inventory we calculated the median ECOL, ES and TOT values of the species checklist and the overall ECOL, ES and TOT values (by

summing). Finally, we fitted a linear mixed model to predict each of the inventory values of ECOL, ES and TOT (median and overall) with the management type (AB, RL or IN). The model included SITE as random effect. Post-hoc multiple comparisons Tukey tests with Bonferroni-Holm correction for each model were eventually performed. All analysis were run in R (version 4.0.2) with the ‘vegan’ (Bray-Curtis dissimilarity and ANOSIM), ‘stats’ (hierarchical clustering), ‘lme4’ (linear mixed models) and ‘multcomp’ (post-hoc Tukey tests) packages.

Table 1 – Description of the ecosystem services indicators (ecological and ecosystem service value) considered for each of the plant species observed. For each indicator the proxy, the range or the values assigned to the different levels of the indicators and the source is provided. Only for ES indicators, the CICES code (Common International Classification of Ecosystem Services code, V5.1) is provided (Haines-Young and Potschin, 2018).

INDEX	INDICATOR	CICES CODE	PROXY	RANGE/VALUES	SOURCE

Results

A total of 332 plant species belonging to 54 families were identified through the field monitoring. The full checklist is shown in SM1. The list includes one species classified as EN by the Lebanese Red List of Plants, namely *Orchis anatolica*, and 3 classified as NT (*Papaver rhoeas*, *Orchis italica* and *Scorzonera mollis*). 54 species are Lebanese or Levantine endemisms, including *Salvia judaica*, *S. hierosolymitana*, *Centaurea cheirollopha*, *Geranium libanoticum*, *Orchis galilaea*, *O. anatolica*. Almost half of the species were specific to single management types (54 species specific to AB sites, 53 to RL sites and 53 to IN sites). 161 species were not found in IN sites. Overall, 212 species were observed in RL sites, 188 in AB sites and 177 in IN sites.

Inventories' species richness was highest in the AB, followed by RL and IN (Figure 2). The model's total explanatory power is substantial (conditional $R^2 = 0.35$). IN sites diversity was significantly lower than AB sites (beta = -11.11, 95% CI [-18.60, -3.61], $t(107) = -2.94$, $p = 0.004$). Conversely, RL site diversity is comparable to AB sites (beta = -0.39, 95% CI [-8.23, 7.45], $t(107) = -0.10$, $p = 0.922$). In addition, post-hoc Tukey test show significant lower diversity of IN sites with respect to RL sites (RL – IN, estimate=10.71, $z=2.725$, $p=0.018$).

The results of the hierarchical clustering are shown in Figure 3. The Bray-Curtis dissimilarity among managements show a continuum of the differences of species assemblage among sites. However, 4 main clusters can be outlined. A first cluster (blue) is represented by an only AB site, which stands out as a possible outlier. Two other clusters (green and red) include IN sites only, but one RL site, which is the most distantly related within the cluster. The fourth cluster (gold) includes all the remaining AB and RL sites. In this large cluster, 3 sub-clusters are seen, 2 including AB sites only and 1 including RL and one AB sites. The results of the analysis of similarity are consistent with the cluster analysis. ANOSIM statistic R was 0.283 ($p=0.001$), which indicates a moderate dissimilarity of plant communities between managements. Dissimilarities ranks within-classes show that dissimilarity is highest among RL sites (50% percentile=84.7) and lowest in IN sites (50%=36.0). In addition, within-class RL dissimilarity rank is higher than the between-classes dissimilarity rank (Figure 4).

ECOL, ES and TOT indices values were on average highest in the inventories performed in the AB sites, followed by RL sites and IN sites (Figure 5). Mixed-models results are shown in Table 2. ECOL, ES and TOT inventory overall values were significantly higher in AB sites compared to IN sites (respectively, ECOL: estimate +7.28, $p=0.001$; ES: estimate +2.98, $p=0.037$; TOT: estimate +10.26, $p=0.003$), while differences between AB and RL were marginal and never significant. Post-hoc tests show that values of ECOL and TOT indices are also significantly higher in RL sites compared to IN sites (ECOL: estimate +6.35, $p=0.008$; TOT: estimate +9.54, $p=0.017$), while ES value approached statistical significance (estimate +3.17, $p=0.078$). As for median inventory values, no significant differences emerge, with the exception of ECOL values between AB and IN sites (estimate +0.08, $p=0.002$). ECOL values differences approached statistical significance also in the RL-IN comparison (estimate +0.05, $p=0.076$).

Figure 2 – Distribution of species richness values in inventories across terraces management types. Brackets indicate statistical significance as derived from post-hoc Tukey test of linear mixed model (* < 0.05; ** < 0.01; ns, not significant). Discussion

The restoration of abandoned terraces plays a critical role in terms of maintaining biodiversity and increasing human well-being. Our study shows that restoration of terraces in the SBR is associated to diversity values, ecological function and ecosystem service values within the same range as the naturally-rewilded abandoned terraces. All the results show that species assemblage of RL sites appears more closely related to AB sites than to IN sites, despite the agricultural land use. IN sites display low levels of diversity and ecological functions, confirming the lower suitability of intensive farming in achieving biodiversity conservation goals and in providing adequate levels of ecosystem services.

Plant diversity was significantly highest in the inventories performed in AB sites and lowest in IN sites. In fact, land abandonment in Mediterranean ecosystems is usually

associated with secondary ecological succession towards semi-natural grassland with an increase of species abundance, even if responses may differ in effect size according to climate, spatial-temporal scales, land uses and landforms (Plieninger et al., 2014). Bonet (2004) showed that quick turnover of functional groups (annual/biennial plants, perennial forbs, perennial grasses etc.) occurs after few years of abandonment, which causes the presence of species rich communities resulting from niche overlap (Cody, 1991) or different disturbance regimes (Lavorel et al., 1999). However, diversity usually reaches a peak in 10-20 years before declining (Bonet, 2004; Debussche et al., 1996). It must be noted that species diversity in RL sites was not statistically different from AB sites at inventory level and that the overall checklist of RL sites included even 24 more species than AB sites. Conversely, intensive agricultural practices such as ploughing, fertilization, weed control and watering represent disturbances that may reduce significantly plant diversity in IN sites, favouring few, stress-resistant, generalist plant species. Low-input agriculture applied to restored terraces in accordance with the FLR principles allows the development of plant-rich communities closely related to naturally-rewilded abandoned terraces in terms of both species diversity and species assemblages. Hierarchical clustering reveals in fact that RL sites communities are hardly distinguishable from AB sites, while IN sites display communities easily identified and classified within parent clusters. Taxonomic similarity of AB and RL sites can also be explained by the presence of rare species, which are known to drive species assemblage differences in Mediterranean agricultural (Tarifa et al., 2021). Among the 11 species of orchids observed, 10 were found in AB sites, 3 in RL and none in IN sites. Lebanese, Levantine or Eastern Mediterranean endemism were more abundant in AB sites (66 species) compared to RL (54) and IN sites (38). Agricultural intensification erodes rare species, either as direct consequence of management practices (e.g. ploughing, use of herbicides) or indirectly (e.g. by reducing pollinators with pesticides and, hence, insect-pollinated plants) (Pinke and Gunton, 2014). Consistently with the cluster analysis, the ANOSIM shows that within-site similarity of IN sites is highest and way higher than between-site similarity. AB terraces display a similar pattern, while, conversely, RL sites plant communities are possibly more diverse. This result may suggest that species assemblages in IN sites are mostly driven by fewer, typical species adapted to high disturbance regimes, while AB sites consistently feature semi-natural grassland species. Low similarity across RL terraces hints at species assemblages influenced by spillovers from the remainder communities.

As expected, our study shows that AB and RL sites provide high-value ecological and ES plant communities compared to IN sites. The difference resides chiefly in species' ecological value, which in AB sites is significantly higher on a species' average basis compared to IN sites (and approaching significance between RL and IN). Thus, semi-natural abandoned terraces and low-input farming terrace systems positively contribute to the preservation of biodiversity, by hosting plant species of intrinsically higher value, such as endemic, endangered, habitat-specific or insect-pollinating species. The effect is boosted by the higher diversity of species found with respect to intensively-managed terraces. All things considered, restoring terraces has no negative effects on biodiversity conservation in SBR. Conservation goals, sustainable production and food security can be achieved by applying FLR principles, restoring economic and social functions of the landscape while maintaining ecological functionality (Beatty et al., 2018; Hani et al., 2019). In Mediterranean landscapes, agroforestry was already shown to enhance biodiversity and ES relative to conventional agriculture, including the practice of integrating cover crops in olive orchards to increase nutrient retention and to prevent soil erosion (Durán Zuazo & Rodríguez Pleguezuelo, 2008; Gómez et al., 2009; Torralba et al., 2016). Conversely, no differences were seen from a plants' qualitative point of view (plants' median ES value in inventories), but rather differences stood out quantitatively at terrace level. In fact, as far

as plants' overall ES value in inventories are considered, the effect of the larger species' abundance in AB and RL sites determined significant higher ES values in AB and RL sites. Non-linear relationship between qualitative and quantitative aspects of ES have already been demonstrated in farmlands (Tzilivakis et al., 2019); however, ecosystem services are provided by ecosystems quantitatively (Lee and Lautenbach, 2016; Logsdon and Chaubey, 2013; Rositano and Ferraro, 2014). It was shown that the relationship between land use and ecosystem services is not linear for each of the 3 categories (provisioning, regulating, cultural). On a gradient between fully natural and fully urban environments, only regulating services reach their maximum values when naturalness is maximized; conversely, cultural (including tourism and recreation) and provisioning services values are maximised at light or extensive land uses (Braat and ten Brink, 2008). In our study, we found mixed results in this sense. IN sites provided higher values in provisioning and regulating services such as pasture enrichment and food, while cultural values (chiefly, aesthetic values) were mostly present in AB and RL sites. Possibly, the selection of the ES indicators may not have included all the wide range of ES provided by ecosystems in the different categories. In addition, smallholder farmland system, such as the one featured in the SBR, may also contribute to plant species' spillovers from semi-natural and low-input patches to more intensively-managed terraces, partially buffering negative effects of invasive farming practices (Concepción et al., 2012).

Conclusions

The restoration of abandoned terraces in the SBR, which applies FLR restoration principles such as agroforestry and low-input agriculture, is effective in maintaining same biodiversity levels of naturally-rewilded abandoned terraces whilst producing agricultural products, income for the local communities and well-being. The study gives evidence that restoring abandoned terraces is a win-win nature-based solution (NbS) which is able to combine the same ecological functionality of semi-natural environments with the provision of primary food production and well-being.

Acknowledgements

We are grateful to the landowners of the monitoring sites for allowing monitoring activities in their farmlands. We also thank two anonymous reviewers for improving the manuscript.

Acknowledgement of financial support: This research was performed under the framework of the “STONE - Restoration and valorization of traditional agricultural systems for economic development and environmental conservation of the Shouf Biosphere Reserve” project, funded by the AICS - Italian Agency for Development and Cooperation. Supplementary material 1

Checklist of the plant species identified in the SBR terraces with their respective ECOL and ES values. Numbers refer to the species' frequency (n max=6) in the different terrace typologies (RL=restored terraces; AB=abandoned terraces; IN=intensively-managed terraces)

SPECIES	RL	AB	IN	ECOL	ES
<i>Adonis annua</i> L.	1			0.563	0.667
<i>Aegilops neglecta</i> Req. Ex Bertol.	3	4	2	0.188	0.524
<i>Aegilops triuncialis</i> L.	2	2		0.188	0.381
<i>Aegilotriticum loretti</i> (K.Richt.)P.Fourn.			1	0.125	0.238
<i>Ajuga chamaepitys chia</i> (Schreb.) Arcang.	4	1		0.375	0.238
<i>Alcea kurdica colesyriaca</i> (Mouterde) Mouterde		1		0.563	0.095
<i>Alcea setosa</i> (Boiss.) Alef.	1	1	1	0.625	0.667
<i>Allium neapolitanum</i> Cirillo	2			0.563	0.714
<i>Allium rotundum</i> L.	1			0.500	0.429
<i>Allium trifoliatum</i> Cirillo	3		1	0.625	0.571
<i>Alopecurus myosuroides</i> Huds.	3		2	0.188	0.238
<i>Alopecurus rendlei</i> Eig.	2			0.188	0.238
<i>Alopecurus utriculatus</i> Sol.	2		4	0.375	0.238
<i>Alyssum repens</i> Baumg.		1		0.625	0.143
<i>Amaranthus retroflexus</i> L.	1		2	0.000	0.143

Supplementary material 2

Here below the checklist of species found in each sampling site is reported

Site S01_AB

Aegilops neglecta
Ajuga chamaepitys
Anacamptis papilionacea
Anacamptis pyramidalis
Anagallis arvensis
Anchusa hybrida
Anemone coronaria
Anisantha sterilis
Anthemis chia
Arum palaestinum
Asparagus acutifolius
Asphodelus ramosus
Avena clauda
Avena sterilis
Bituminaria bituminosa
Carduus argentatus
Carduus pycnocephalus
Carlina curretum
Carthamus tenuis
Catananche lutea
Centaurea iberica
Cirsium phyllocephalum
Convolvulus arvensis
Cota tinctoria
Crepis aspera
Crepis foetida
Crepis hierosolymitana
Cyclamen persicum
Dactylis glomerata
Dactylorhiza urvilleana
Daucus carota
Dittrichia viscosa
Echinops adenocaulos
Erodium malacoides
Eryngium creticum
Eryngium glomeratum
Erysimum scabrum
Fibigia clypeata
Geranium libanoticum
Geropogon hybridus
Gladiolus italicus
Hordeum bulbosum
Hymenocarpus circinnatus
Hypericum triquetrifolium
Hypochaeris achyrophorus
Isatis lusitanica
Lathyrus blepharicarpus

Leopoldia comosa
Linum pubescens
Linum strictum
Lolium perenne
Medicago sativa varia
Neotinea tridentata
Notobasis syriaca
Ononis spinosa
Orchis anatolica
Pallenis spinosa
Peltaria angustifolia
Picnemon acarna
Pimpinella peregrina
Plantago lanceolata
Polygala monspeliaca
Pyrus syriaca
Quercus coccifera
Rubia tenuifolia
Salvia viscosa
Sanguisorba minor
Sanguisorba verrucosa
Sarcopoterium spinosum
Securigera securidaca
Silene vulgaris
Spartium junceum
Stachys cretica
Torilis tenella
Tragopogon porrifolius
Trifolium angustifolium
Trifolium clusii
Trifolium scabrum
Trifolium stellatum
Vicia sativa

Site S02_AB

Aegilops neglecta
Alyssum repens
Anacamptis papilionacea
Anagallis arvensis
Anchusa hybrida
Anemone coronaria
Anisantha sterilis
Anthyllis vulneraria
Arum palaestinum
Avena clauda
Avena sterilis
Bituminaria bituminosa
Bromus brachystachys

Bunium pestolazzae
Calicotome villosa
Carduus argentatus
Carlina curetum
Catananche lutea
Centaurea iberica
Cirsium phyllocephalum
Cota tinctoria
Crepis reuteriana reuteriana
Crupina crupinastrum
Cyclamen persicum
Dactylis glomerata
Daucus carota
Echinops adenocaulos
Eremostachys laciniata
Eryngium glomeratum
Ficus carica
Galium hierosolymitanum
Geranium libanoticum
Gladiolus italicus
Heptaptera anisoptera
Heptaptera microcarpa
Hordeum bulbosum
Hypericum triquetrifolium
Hypochaeris achyrophorus
Klasea cerinthifolia
Lathyrus blepharicarpos
Leopoldia comosa
Linum pubescens
Linum strictum
Lomelosia palaestina
Lotus judaicus
Marrubium cuneatum
Muscari neglectum
Neotinea tridentata
Ononis viscosa
Orchis anatolica
Pallenis spinosa
Pimpinella peregrina
Polygala monspeliaca
Pterocephalus plumosus
Rosa canina
Rubia tenuifolia
Sanguisorba verrucosa
Sarcopoterium spinosum
Securigera securidaca
Senecio leucanthemifolius
Silene damascena
Spartium junceum
Stachys cretica
Torilis tenella
Trifolium campestre

Trifolium stellatum
Vicia sativa
